The precise effects of these factors may be difficult to quantify in terms of stress or strength. In addition, many of these characteristics are difficult to detect or evaluate by analytical methods. For these and other reasons (related to dimensional and operational variables), substantial reliance should be placed on representative durability testing during certification of drive system and structural reciprocating engine parts. c. These factors should also be considered when the extent of the redesign is limited to a change in material. A1-2. Factors That Increase Stress. The following factors may affect mean (steady state) stresses and operational (dynamic) stresses: a. Surface treatment processes (such as carburizing, nitriding, and shot peening) that introduce beneficial surface stresses may also cause increased residual tensile stresses in the core. This can be especially significant in thin sections of parts. b. Prestress in bolted joints, which is generally beneficial if it is not excessive. c. Straightening, which can result in residual stresses and risk of cracking. d. Welding or brazing, which can cause residual stresses. e. Dimensional changes. f. Interference fits (assembly stresses). g. Reduced cross-sectional areas, including wall thicknesses, which can cause increased operational stresses and mean stresses. h. Manufacturing-related stress raisers, which can cause increased operational stresses. Manufacturing processes that produce surface stress raisers should normally be discovered during examination of test articles by visual observation and crack inspection procedures. Subsurface stress raisers resulting in material strength issues are largely controlled...
